Abstract. In this paper a model for the prediction of the ultimate axial compressive capacity of square and rectangular Concrete Filled Steel Tubes, based on an Artificial Neural Network modeling procedure is presented. The model is trained and tested using an experimental database, compiled for this reason from the literature that amounts to 1193 specimens, including long, thin-walled and high-strength ones. The proposed model was selected as the optimum from a plethora of alternatives, employing different activation functions in the context of Artificial Neural Network technique. The performance of the developed model was compared against existing methodologies from design codes and from proposals in the literature, employing several performance indices. It was found that the proposed model achieves remarkably improved predictions of the ultimate axial load.

Keywords: artificial neural network; CFST column; soft computing; ultimate axial load

1. Introduction

Steel is widely used for various structural components in the construction industry including civil, industrial, bridge, hydraulic etc. (Ali *et al.* 2016, Caprili and Salvatore 2015), due to its key properties that prove valuable in practice, such as high tensile and compressive strength, enhanced ductility, reliability as well as speed of construction (Zhao *et al.* 2015). However, the main disadvantage of structural steel is that it can be susceptible to corrosion and also the high cost of material (Young 2008). For example, a bare steel pipe under compression is susceptible to various instabilities, namely flexural buckling, local buckling etc. however, filling the pipe with concrete certain advantages are obtained. The corrosion resistance of the inner surface is enhanced, the buckling capacity as well as the local stability of the pipe walls against inward movement are increased and additionally, an elevated resistance to distortions, due to impact, is achieved (Khan *et al.* 2017). For the concrete core on the other hand, confinement is offered by the steel pipe, which also serves as formwork.

Steel tubes filled with concrete have shown many advantages in the literature and are widely used in many fields (Khanouki *et al.* 2016, Giakoumelis and Lam 2004). They are typically called concrete-filled steel tubes (CFSTs), and offer high strength and stiffness, large energy absorption capacity, high axial load capacity, attractive

appearance, increased fire resistance, excellent ductility, and low strength degradation (Giakoumelis and Lam 2004). Having these characteristics, CFST components can be widely applied in many types of structures and loading conditions (Han and Yang 2001); for example as columns in high-rise buildings, in bridges (pylons, abutments, arch ribs, piers), and even in regions of high seismic risk (Tao *et al.* 2016, Song *et al.* 2017, Chang *et al.* 2012, Han *et al.* 2005, Baig *et al.* 2006). Notably, numerous bridges built in China have been using CFST-type components; for instance, 413 bridges with a span of no less than 50m were built in 2015 (Liu *et al.* 2019). In particular, CFST structures prove highly effective when subject to compression (Ren *et al.* 2019).

The maximum bearing capacity of CFST columns depends on the properties and behavior of its constituent materials. In addition, the behavior of columns depends on the geometric properties of the steel pipe, such as the width-to-thickness ratio and the confining effect of the steel pipe on the concrete core. The cross-sectional forms of the selected column CFST are usually symmetrical, either circular or square or rectangular (Han *et al.* 2014). The CFST columns with square and rectangular shapes are commonly used in construction, as they provide easier manufacturing process for the beam to column joints and achieve higher bending stiffness (Ren *et al.* 2019, Zhao *et al.* 2015). However, when compared to circular CFST columns, they do not offer the same confinement conditions and the potential for delamination of the concrete from the steel tube, under working loads, is increased (Krishan *et al.* 2016, Bradford *et al.* 2002, Goel and Tiwary 2018). It is well known that the bond-slip between the concrete core and the steel tube has a crucial effect on the mechanical

behavior, failure mode, and the working performance of the CFST members.

In the past decades, many studies of the bearing capacity and behavior of the CFST have been performed, focusing on their mechanical properties under axial compression. In Schneider (1998), a total of fourteen samples were used to evaluate the effect of wall thickness and the steel tube shape on the composite column ultimate strength, considering the parameters of the ratio of depth to tube wall thickness and the shape of the steel tube. The experimental results suggested that current design specifications are not sufficient for predicting the yield load for various structural shapes. Fam *et al.* (2004) carried out experimental work and analytical modeling of CFSTs subject to concentric axial compressive as well as lateral cyclic loading. Ten samples were tested; five short CFST column samples and five CFST beam-column samples. The results indicated that the bond and the end loading conditions had no significant influence on the flexural strength of beam-column members. Other studies also performed experimental tests focusing on the behavior of the CFST columns under the axial load (e.g., Ibanez *et al.* 2021, Yu *et al.* 2007, Han *et al.* 2012, Asteris *et al.* 2021c).

In addition, numerical simulations have been developed and widely applied in investigating the behavior of CFST columns under axial compression. For example, Dai *et al.* (2010) utilized Finite Element Modeling (FEM), to simulate the elliptical CFST columns under axial compression. Choi *et al.* (2009) described a numerical program for analyzing the behavior of the tubular CFST columns and predicting different modes of lateral interactions between the concrete and the steel tube under axial compression. It is worth noting that in such numerical simulations, it is laborious to take into account all material properties and interactions, in order for the models to be able to predict the behavior of the CFST columns, under various loading conditions and with a reasonable precision (Sarir *et al.* 2019b). From previous studies, many well-known national standards and recommendations proposed various practical design formulas in order to characterize the behavior of the CFST columns, namely Chinese code DBJ 13-51-2010 (2010), Australian code AS5100 (2004), American code AISC 360 (2016), Japanese code AIJ (1997), and European code EN1994 (2004). Moreover, other simplified calculation formulas have also been proposed, for instance, Yu *et al.* (2013) proposed a unified formula to calculate the axial load-bearing capacity of the circular or polygonal CFST columns. However, most simplified methodologies suffer from limited application scope and/or accuracy, preventing them from widespread use. Therefore, the development of robust and accurate methods for multiple applications are required to be able to calculate with confidence the final load-bearing capacity of the CFST columns.

Artificial Intelligence (AI) and machine learning have been developed and applied in many different fields with high precision and effectiveness (Ahmadi *et al.* 2017, Psyllaki *et al.* 2018, Kechagias *et al.* 2018, Huang *et al.* 2019, Apostolopoulou *et al.* 2019, 2020, Armaghani *et al.* 2020, Armaghani and Asteris 2021, Asteris *et al.* 2021a, 2021b, Zeng *et al.* 2021, Zhang *et al.* 2021). Out of these,

Table 1 Field of application of examined design codes regarding CFST axial compressive strength

Code	Limits
EN1994 (2004)	$235 \leq f_y \leq 460$
	$25 \leq f_c' \leq 50$
	$H/t \leq 52\sqrt{(235/f_y)}$
AISC 360 (2016)	$f_y \leq 525$
	$21 \leq f_c' \leq 69$
	$H/t \leq 5\sqrt{(E_s/f_y)}$
AIJ (1997)	$235 \leq f_y \leq 355$
	$18 \leq f_c' \leq 60$
	$H/t \leq 1102.5/\sqrt{\min\{f_y; 0.7f_u\}}$
AS5100 (2004)	$f_y \leq 350$
	$25 \leq f_c' \leq 65$
	$H/t \sqrt{(f_y/250)} \leq a$

where a depends on tube manufacturing

Artificial Neural Network (ANN), which uses existing experimental data to train neural networks in order to study the behavior of the materials and structures under various testing conditions, has become the most commonly used machine learning algorithm (Jegadesh and Jayalekshmi 2015, 2015b). Many studies related to ANN on the behavior of steel-concrete pipe columns, subject to different types of loads have been conducted, such as the estimation of fire resistance of tubular CFST columns (Al-Khaleefi *et al.* 2002); study of biaxial bending behavior of steel-concrete composite beam-columns (Behnam and Esfahani 2018) and ultrasonic testing CFST (Xiao 2012). Du *et al.* (2017) utilized ANN to estimate the axial bearing capacity of rectangular CFST columns, considering various input parameters, namely sectional width, length and thickness, steel and concrete strength. In such a study, a total of 305 experimental samples were collected, and the results showed that the predicted values are more accurate compared to ACI-318 (2014) and EN1994 (2004). Focusing on the same problem, a growing number of works employs soft computing techniques, including Duong *et al.* (2020), Ly *et al.* (2021), Asteris *et al.* (2021a), Ho and Le (2021). An in-depth state-of-the-art review on the behavior of CFST columns has been recently published by Sarir *et al.* (2019a), where two ANN-based hybrid metaheuristic models were presented, optimized by whale optimization algorithm (WOA) and particle swarm optimization (PSO). Validation and comparison results confirmed the effective role of the WOA in optimization of the proposed hybrid model (ANN-WOA) to predict the bearing capacity of CFST columns.

In the present study, available experimental results for the ultimate axial loads of rectangular concrete-filled steel tubes (CFST) are selected and incorporated within a database of tested specimens.

2. Research significance

Structural engineers spend significant amount of time in preliminary design stage and optimization. Artificial Neural Network (ANN) has been emerging quickly in the research field, but more practical examples are required to increase

Fig. 1 Schematic representation of the biological neuron structure (Asteris et al. 2019)

confidence is using it while ANN has becoming popular in the ACE sector. This study evaluates the feasibility of ANN in designing CFST columns used in the building construction sector to help increase the efficiency in design stages. ANN has been selected as it has the ability to learn and model non-linear and complex relationship which fits to most structural design problems. The evaluation of the feasibility to utilize ANN is important for the future of structural design as Artificial Intelligence (AI) models can optimize and predict, as well as increase the efficiency at preliminary design stage.

3. Brief literature review on available proposals

Many steel and composite codes cover the design of CFST columns subject to axial compression. These include the European code EN1994 (2004), the American codes AISC 360 (2016) and ACI-318 (2014), the Japanese code AIJ (1997), the Australian code AS5100 (2004), and the Chinese code DBJ 13-51-2010 (2010). All codes limit their field of application, typically in regard to steel strength f_y , concrete strength f'_c and steel section slenderness. Table 1 presents these limits for EN1994 (2004), AISC-360 (2016), AIJ (1997) and AS5100 (2004), that will be utilized in this

Fig. 2 Rectangular CFST under uniaxial compressive load

work for comparison against the proposed ANN methodology, later in the text. It can be seen that a significant range of high strength steels and concretes is not covered by the codes. AISC-360 (2016) is the most

inclusive one, particularly regarding steel.

All examined codes provide procedures for validating the squash load of CFST using a combination of the plastic strengths of the steel and concrete parts. For slender steel sections however, the ultimate compressive capacity is restricted by the local buckling phenomena of the tube walls. On the other hand, for long columns, the ultimate load is probably determined by member buckling. axial compressive load. The selected codes provide methodologies for the characterization of local or global buckling phenomena. Taking into account that the specimens in our experimental database, that will be presented later in the text, contain both long tubes and thin-walled ones, this remark is considered crucial for a fair comparison between the design codes. Safety factors are not

included in the presented formulas. Appendix presents the relevant formulas available in the four selected design codes for the calculation of the CFST capacity, under.

A significant number of proposals is also available in the literature for the estimation of the axial ultimate load of square and rectangular CFSTs. Among others, Sakino *et al.* (2004) proposed a strength reduction factor, for square shaped tubes, accounting for local instabilities. Han *et al.* (2005), provided an expression for the squash load of square and circular CFSTs. Wang *et al.* (2017) proposed a simplified model for the prediction of the ultimate axial load of circular and rectangular CFST columns, accounting for concrete confinement and tube slenderness. Also, for high strength steel, Du *et al.* (2016) calibrated an expression for the ultimate load of CFSTs. Table 2 summarizes these

expressions available in the literature, in the case of rectangular tubes, that is the scope of this work.

4. Materials and methods

4.1 Brief review on artificial neural networks

Artificial neural networks (ANNs) are based on the concept of the biological neural network of the human brain. The basic building block of ANNs is the artificial neuron, which is a mathematical model aiming to mimic the behavior of the biological neuron (Fig. 1). Information is passed into the artificial neuron as input and is processed with a mathematical function leading to an output that determines the behavior of the neuron (similar to fire-or-not situation for the biological neuron). Before the information enters the neuron, it is weighted in order to approximate the random nature of the biological neuron. A group of such neurons consists of an ANN, in a manner similar to biological neural networks. In order to set up an ANN, one needs to define: (i) the architecture of the ANN; (ii) the training algorithm, which will be used for the ANN's learning phase; and (iii) the mathematical functions describing the mathematical model.

The architecture or topology of the ANN describes the manner in which the artificial neurons are organized in the group and how information flows within the network. For example, if the neurons are organized in more than one layer, then the network is called a multilayer ANN. The training phase can be considered as a function minimization problem, in which the optimum values of weights need to be determined by minimizing an error function. Depending on the optimization algorithms used for this purpose, different types of ANNs exist.

The gradient descent (GD) method is employed mainly in the back-propagation (BP) stage of the training process of the ANN model (Rumelhart *et al.* 1986). The main working principle of the GD is to adjust the weights of the ANN model iteratively while minimizing the error between the actual output and target (Du and Swamy 2013). However, using GD may result to convergence problems (Gupta *et al.* 2013) (i.e., time-consuming training process). Many more training algorithms have been proposed to enhance the effectiveness of ANN training, one of them is the Levenberg-Marquardt (LM) method (Marquardt 1963), which has been commonly used in various studies of different fields (Raghuwanshi *et al.* 2006, Aqil *et al.* 2007, de Vos and Rientjes 2008, Taormina *et al.* 2012). The speed of convergence when using the LM technique has been improved due to the method that was developed by combining the GD and Gauss-Newton (GN) algorithms (Marquardt 1963). More recently, a number of training algorithms that use the second derivative have been proposed in the literature. These are the One-Step Secant (OSS) (Battiti 1992), the Gradient Descent with Adaptive Learning Rate (GDA) (Kayacan and Khanesar 2015), the Scaled Conjugate Gradient (SCG) (Møller 1993), and the Conjugate Gradient Backpropagation with Powell-Beale Restarts (CGB) (Powell 1977). However, second-order

learning techniques require to be used in a batch mode due to the sensitivity of the numerical computation of second-order gradients (Akbar *et al.* 2011, Du and Swamy 2013). In addition, learning algorithms based on the first and second-order derivative may not have the required convergence ability if the starting point is located outside of the search domain (Brownlee 2016). The foresaid learning algorithms contributed to the progress in training ANN methods, for better performance of the prediction models.

4.2 Performance Indices

Three different statistical parameters were employed to evaluate the performance of the derived computational model as well as the available in the literature formulae, including the root mean square error (RMSE), the mean absolute percentage error (MAPE), and the Pearson Correlation Coefficient R^2 . The lower RMSE and MAPE values represent the more accurate prediction results. The higher R^2 values represent the greater fit between the analytical and predicted values. The aforementioned statistical parameters have been calculated by the following expressions (Alavi and Gandomi 2012):

$$RMSE = \sqrt{\frac{1}{n} \sum_{i=1}^n (x_i - y_i)^2} \quad (1)$$

$$MAPE = \frac{1}{n} \sum_{i=1}^n \left| \frac{x_i - y_i}{x_i} \right| \quad (2)$$

$$R^2 = 1 - \left(\frac{\sum_{i=1}^n (x_i - y_i)^2}{\sum_{i=1}^n (x_i - \bar{x})^2} \right) \quad (3)$$

where n denotes the total number of datasets, and x_i and y_i represent the predicted and target values, respectively.

The reliability and accuracy of the developed neural networks were evaluated using Pearson's correlation coefficient R and the root mean square error (RMSE). RMSE presents information on the short-term efficiency which is a benchmark of the difference of predicted values in relation to the experimental values. The lower the RMSE, the more accurate is the evaluation. The Pearson's correlation coefficient R measures the variance that is interpreted by the model, which is the reduction of variance when using the model. R values range from 0 to 1, however the model has healthy predictive ability when it is near to 1 and it is not predicting when near to 0. These performance metrics are a good measure of the overall predictive accuracy.

Furthermore, the following new engineering index, called a20-index, has been proposed for the reliability assessment of the developed ANN models (Asteris *et al.* 2019, Asteris and Mokos 2020, Asteris *et al.* 2021d):

$$a_{20-index} = \frac{m_{20}}{M} \quad (4)$$

where M is the number of dataset sample and m_{20} is the number of samples with value of rate Experimental value/Predicted value between 0.80 and 1.20. Note that for a perfect predictive model, the values of a20-index values are

Fig. 3 Histograms of the parameters: Length of Tubes Section (B); Height of Tubes Section (H) and Thickness of Tubes Section (t)

expected to be unity. The proposed a_{20} -index has the advantage that their value has a physical engineering meaning. It declares the amount of the samples that satisfies predicted values with a margin $\pm 20\%$ compared to experimental values.

4.3 Data used and selection of variables

It should be noted that the term “sufficient amount of data” does not necessarily imply a high amount of data, but rather datasets that cover a wide range of combinations of

input parameter values, thus assisting in the model capability to simulate the problem. The demand for a reliable database is particularly crucial in the case of experimental databases, which are databases compiled using experimental results. In this case, significant deviations between experimental values are frequently noticed, not only between experiments conducted by different research teams and laboratories, but even between datasets derived from experiments conducted on specimens of the same synthesis, produced by the same technicians,

Fig. 4 Histograms of the parameters: Effective Length of Steel Tube Column (L_e); Steel Yield Strength (f_y) and Concrete Compressive Strength (f_c')

cured under the same conditions and tested implementing the same standards and the same testing instruments.

In light of the above discussion, an experimental database comprising 1193 datasets was compiled from research papers reported in the literature dealing with the behavior of rectangular concrete-filled steel tubes under axial load without any eccentricity (Fig. 2).

Table 3 presents in detail the number of samples and the range of ultimate axial load for each one of the 73 experimental works used for the compilation of the database which will be used for the development and training of the soft computing model in the context of the artificial neural network technique. Each dataset comprises of six input parameters (Width of Tube Section (B), Height of Tube

Fig. 5 Histograms of the parameters of the ultimate axial load (N)

Section (H), Thickness of Tube (t), Effective Length of Column (L_e), Steel Yield Strength (f_y) and Concrete Compressive Strength (f_c) and the ultimate axial load (N) as the output parameter. Table 4 shows the minimum average and maximum values, as well as the standard deviation of the input and output parameters respectively, while Table 5 presents the correlation matrix of the input and output parameters. The histograms for each of the input and output parameters are presented in Figs. 3 to 5.

4.4 Sensitivity analysis

In general, sensitivity analysis (SA) of a numerical model is a technique used to determine if the output of the model is affected by changes in the input parameters. This provides feedback regarding which input parameters are the most significant, and thus, by removing the insignificant ones, the input space will be reduced and subsequently the complexity of the model, as well as the time required for its training, will be also reduced. In order to identify the effects of model inputs on the outputs, the SA can be conducted on the database. Sometimes, the results of SA help researchers/designers to remove one or more input parameters from the database to obtain better analyses with a higher level of performance prediction. To perform the SA, the cosine amplitude method (CAM), is employed, which has been used by many researchers (Armaghani and Asteris 2021, Armaghani *et al.* 2015, 2020, Momeni *et al.* 2015, Asteris *et al.* 2021). In CAM, data pairs may be used to construct a data array, X , as follows:

$$X = \{x_1, x_2, x_3, \dots, x_i, \dots, x_n\} \quad (5)$$

Variable x_i in array, X , is a length vector of m as:

$$x_i = \{x_{i1}, x_{i2}, x_{i3}, \dots, x_{im}\} \quad (6)$$

The relationship between R_{ij} (strength of the relation) and datasets of X_i and X_j is presented by the following equation:

$$R_{ij} = \frac{\sum_{k=1}^m x_{ik}x_{jk}}{\sqrt{\sum_{k=1}^m x_{ik}^2 \sum_{k=1}^m x_{jk}^2}} \quad (7)$$

Fig. 6 Sensitivity analysis of Axial Load Capacity of Rectangular Concrete-filled Steel Tube Columns

The R_{ij} values between the Axial Load Capacity of Rectangular Concrete-filled Steel Tube Columns and the input parameters are shown in Fig. 6. This analysis reveals that, the width and the height of the steel tube cross section have the greatest influence on axial load capacity values, with strength values of 0.8841, followed by steel yield strength, f_y (0.8550), thickness of tube walls, t (0.8540), concrete compressive strength, f_c (0.7852). The parameter with the lowest influence on axial load capacity seems to be the effective column length, L_e (0.5614).

5. Results and discussion

5.1. Development of ANN models

Based on the above, different architecture ANNs were developed and trained. More specifically, during the development and training of the ANN models the following steps (which are summarized in Table 6) were followed:

- The 1193 datasets in the database, used for the training and development of the ANN models, were divided into three separate sets. Specifically, 796 of 1193 (66.72%) datasets were

designated as Training datasets, 199 (16.68%) as Validation datasets, while 198 (16.60%) datasets were used as Testing datasets.

- During the training of the ANNs, the above datasets were used with and without normalization. When normalization of the data was conducted, the minmax normalization technique in the range [0.10, 0.90] and [-1.00, 100) as well as the Zscore were implemented.

- The Levenberg–Marquardt algorithm (Lourakis 2005) was used for the training of the ANNs.

- 10 different initial values of weights and biases were

applied for each architecture (Table 6).

- ANNs with only one hidden layer were developed and trained.

- The Number of Neurons per Hidden Layer ranged from 1 to 30, by an increment step of 1.

- Two functions, the Mean Square Error (MSE) and Sum Square Error (SSE) functions were used as cost functions, during the training and validation process.

- 10 functions, as presented in Table, were used as transfer or activation functions

The above steps resulted in the development of 240.000

Table 8 Summary of prediction capability of the optimum BPNN 6-30-1 model against existing methodologies

	Model	Datasets	Performance Indices				
			a20-index	R	RMSE	MAPE	VAF
1	BPNN 6-30-1	Training	0.9209	0.9888	227.37	0.1100	97.78

different ANNs. It is worth noting that only the use of 10 different transfer function results in 100 different ANNs, for each architecture with the same number of neurons, as a result of 100 ($=10^2$) different dual combinations of the 10 transfer functions investigated.

The above developed 240,000 ANNs were ranked based on the value of the RMSE performance index, for the case of Testing Datasets, and the top 20 architectures are presented in Table 7. Among them, the optimum ANN model, based on the value of RMSE of Testing Datasets, is the BPNN 6-30-1 model that corresponds to a NN structure with 30 neurons, and use of zscore normalization technique, while the transfer functions are the Symmetric saturating linear transfer function (SSL) (satlins) for the hidden layer and the Linear transfer function (Li) (purelin) for the output layer.

5.2. Evaluation

Table 8 summarizes the prediction capability of the optimum BPNN 6-30-1 both for training and testing datasets for the five used performance indices (a20-index, R, RMSE, MAPE and VAF). A remarkably high a20-index, over 0.92, indicates that 92% of the specimens were predicted with a margin of error 20%. In the same table, the performance indices of existing methodologies in the design codes and the literature, that were described in a previous section, are also presented, for the Testing datasets. The methodologies are sorted according to their RMSE index. It can be observed that the developed ANN model outperforms existing methodologies for all examined performance indices. Taking into account the Testing Dataset for the comparison, the BPNN 6-30-1 achieves more than 50% reduction of RMSE, compared to the best existing methodology in this regard, which is the proposed by Wang *et al.* (2017). Also, the proposed ANN model records a 20% increase of the a20-index, compared to the Australian AS5100 (2004) code, which performs better among existing methodologies in this index.

Among the design codes, the best RMSE index is achieved by the European EN1994 (2004) code, closely followed by the Japanese AIJ (1997) and Australian AS5100 (2004) ones. In terms of a20-index the AS5100 (2004) and EN1994 (2004) perform quite similar, with a small improvement maintained by the former. American AISC 360 (2016) code achieves the best VAF index among the examined codes however, the remaining indices are worst. Comparing between the methodologies from

the literature, the model from Wang *et al.* (2017) achieves the best indices overall. The model from Sakino *et al.* (2004) follows in terms of RMSE index while the model from Han *et al.* (2005) achieves the second best a20-index. The models from Han *et al.* (2005) and Du *et al.* (2016), which feature simpler formulations, present quite lower RMSE indices.

6. Conclusions

In this paper, a new model for the prediction of the ultimate load of square and rectangular CFSTs under axial compression was presented. The model is based on the ANN technique and employs a number of 30 neurons in a single hidden layer. Its development employed a number of different activation functions and normalization techniques and it was selected as the optimum from 240,000 alternative configurations tested and compared with several performance indices. The following points are the main conclusions from the development procedure:

- The proposed model predicts the ultimate axial load in a quite satisfactory manner offering 20% error margin for 92% of the specimens. Against existing methodologies from the literature and design codes the improvement proves quite significant.
- For the optimum ANN model, it was found that the zscore transfer function provided the better prediction capability compared to liner scaling in a predetermined value ranges that is typically employed. Regarding transfer activation functions the Symmetric Saturating Linear transfer function (SSL) proved more effective for the hidden layer and the Linear transfer function (Li) for the output layer.
- According to results from sensitivity analysis, among the several input variables, the most influencing ones proved the tube dimensions followed by the steel yield limit.

The effective range of input parameters used for the development of the proposed ANN model also defines its valid field of application. Regarding member slenderness, ratios of $L/\min\{B;H\}$ up to 24 have been effectively used, whereas for section slenderness, ratios of $\max\{B;H\}/t$ up to 110. Regarding material properties, steel yield limits up to 820 MPa and concrete strengths up to 115MPa have been effectively used.

An ANN model, even though time consuming to

successfully train, requiring a certain level of expertise in its development, once developed it can be quite valuable in its predictions since it is directly correlated to experimental results. In this context its reliability is always controlled by the range of values of the input variables, available in the experimental database used for its training. Therefore, it is always useful to continually enrich the experimental database with new specimens, so that the reliability of the developed model is further extended and improved.

Nomenclature

ANN(s)	Artificial Neural Network(s)
A_c	Area of Concrete Core Section
A_s	Area of Steel Tube Section
A_{sc}	Area of Composite Section
B	Width of Tubes Section
BPNN	Back Propagation Neural Network
CFST	Concrete Filled Steel Tube
Co	Competitive transfer function
E_c	Concrete Modulus of Elasticity
E_s	Steel Modulus of Elasticity
f_c	Concrete Compressive Strength
f_y	Steel Yield Limit
f_u	Steel Ultimate Strength
GP	Genetic Programming
GUI	Graphical User Interface
H	Height of Tubes Section
HTS	Hyperbolic Tangent Sigmoid transfer function
I_s	Moment of Inertia of Steel Tube Section
I_c	Moment of Inertia of Concrete Core Section
L	Length of Column
L_e	Effective Length of Column
Li	Linear transfer function
LS	Log-Sigmoid transfer function
MAPE	Mean Absolute Percentage Error
MSE	Mean Square Error
N	Axial Load Capacity
N_b	Buckling Capacity of Column
N_{cr}	Elastic Critical Buckling Load
N_{pl}	Squash Load
NRB	Normalized Radial Basis transfer function
PLi	Positive Linear transfer function
R	Pearson correlation coefficient
RB	Radial Basis transfer function
SM	Soft Max transfer function
SSE	Sum Square Error
SP	Superplasticizer
SSL	Symmetric Saturating Linear transfer function
t	Wall Thickness of Steel Tubes
TB	Triangular Basis transfer function
ξ	Confinement Factor
ρ	Concrete Density
$N_u^{predicted}$	Prediction of axial load of CFST columns
[Iw]	Weight matrix of the hidden layer
[bi]	Bias matrix of the hidden layer
[LW]	Weight matrix of the output layer
[bo]	Bias matrix of the output layer
B_{min}, B_{max}	Min and max values of width of tubes sections
H_{min}, H_{max}	Min and max values of height of tubes sections

t_{min}, t_{max}	Min and max values of thickness of tubes sections
L_{min}, L_{max}	Min and max values of effective length of column
f_{ymin}, f_{ymax}	Min and max values of steel yield limit
f_{cmin}, f_{cmax}	Min and max values of concrete strength

BU

Appendix

In Table 9 the expressions provided by the design codes that were utilized in this work are presented, omitting safety factors.

Table 9 Expressions in design codes for the CFST axial compressive strength

Code	Formulas for axial compressive strength
	$N^{EC4} = \chi N_{pl}$
	Where:
EN1994 (2004)	χ depending on $\bar{\lambda}$ and imperfections, $\chi \leq 1$, $N_{pl} = f_y A_s + f'_c A_c$ $\bar{\lambda} = \sqrt{N_{pl}/N_{cr}}$ $N_{cr} = \pi^2 (EI)_{eff} / L_e^2$ $(EI)_{eff} = E_s I_s + 0.6 E_c I_c$
	$N^{AISC360} = \begin{cases} N_{no} \left(0.658^{\frac{N_{no}}{N_{cr}}} \right), & \frac{N_{no}}{N_{cr}} \leq 2.25 \\ 0.877 N_{cr}, & \frac{N_{no}}{N_{cr}} > 2.25 \end{cases}$
	Where:
AISC 360 (2016)	$N_{no} = \begin{cases} N_{pl}, & \lambda < \lambda_p \\ N_{pl} - (N_{pl} - N_y) \frac{(\lambda - \lambda_p)^2}{(\lambda_r - \lambda_p)^2}, & \lambda_p \leq \lambda < \lambda_r \\ 9 E_s A_s / (\lambda^2 + 0.7 f'_c A_c), & \lambda \geq \lambda_r \end{cases}$ $N_{pl} = f_y A_s + 0.85 f'_c A_c$ $N_y = f_y A_s + 0.7 f'_c A_c$ $\lambda = (H - 2t)/t$ $\lambda_p = 2.26 \sqrt{E_s / f_y}, \quad \lambda_r = 3.00 \sqrt{E_s / f_y}$ $(EI)_{eff} = E_s I_s + C_3 E_c I_c$ $C_3 = 0.45 + 3 A_c / A_{sc} \leq 0.9$
	$N^{AIJ} = \begin{cases} A_s f_y + 0.85 A_c f'_c (= N_{pl}), & \lambda \leq 4 \\ N_{pl} - \frac{1}{8} (N_{pl} - N_b) (\lambda - 4), & 4 < \lambda \leq 12 \\ N_b^c + N_b^s (= N_b), & \lambda > 12 \end{cases}$
	Where:
AIJ (1997)	$\lambda = L_e / B$ $N_b^c = \begin{cases} \frac{2}{1 + \sqrt{\bar{\lambda}_c + 1}} 0.85 A_c f'_c, & \bar{\lambda}_c \leq 1 \\ 0.83 e^{[C_c(1 - \bar{\lambda}_c)]} 0.85 A_c f'_c, & \bar{\lambda}_c > 1 \end{cases}$ $N_b^s = \begin{cases} A_s f_y, & \bar{\lambda}_s < 0.3 \\ [1 - 0.545(\bar{\lambda}_s - 0.3)] A_s f_y, & 0.3 \leq \bar{\lambda}_s < 1.3 \\ \pi^2 E_s I_s / (1.3 L_e^2), & \bar{\lambda}_s \geq 1.3 \end{cases}$ $\bar{\lambda}_c = \lambda_c \sqrt{\varepsilon_u^c} / \pi$ $\bar{\lambda}_s = (\lambda_s / \pi) \sqrt{f_y / E_s}$ $\varepsilon_u^c = 0.00093 (0.85 f'_c)^{0.25}$ $C_c = 0.568 + 0.00612 f'_c$
	$N^{AS5100} = a_c N_{pl}$, with $a_c \leq 1$
	Where:
AS5100 (2004)	$N_{pl} = f_y A_s + f'_c A_c$ $N_{cr} = \pi^2 (E_s I_s + E_c I_c) / L_e^2$ $a_c = \xi [1 - \sqrt{1 - (90 / \xi \lambda)^2}]$ $\lambda = 90 \lambda_r + a_a a_b$ $\lambda_r = \sqrt{N_{pl} / N_{cr}}$ $\xi = \frac{(\lambda / 90)^2 + 1 + \eta}{2 (\lambda / 90)^2}$ $a_a = \frac{2100 (90 \lambda_r - 13.5)}{8100 \lambda_r^2 - 1377 \lambda_r + 2050}$ $\eta = 0.00326 (13.5 - \lambda) \geq 0$
